

Both texts address the critical need for standardized data management and documentation. They both present new ways of standardizing data to enhance its reliability.

Gebru claims that data standardization has not been discussed in the machine learning field. They claim that people who make AI do not have a standard way to write down information about their data. This lack causes distribution of incorrect information. They say we need a 'datasheet' (a detailed document) for every dataset. This will help people know where the data came from and use it safely. And, Moretti claims that people in the building industry use closed data systems that cannot talk to each other. Because of this, it is hard to share information. They say we need an open and connected data system. This will help us build 'digital twins' and make better decisions.

These questions occurred to me: Moretti focuses heavily on technical interoperability and data integration across different domains, does their framework need an ethical review layer to prevent the unintended biases and misuse that Gebru highlights?

In my opinion, while Moretti successfully provides the technical architecture necessary to integrate fragmented data across different domains for built environment digital twins, their framework would be vastly improved by incorporating the ethical and qualitative documentation layer proposed by Gebru.
